

# (CLAW, $\vec{C}_3$ )-FREE DIGRAPHS WITH UNBOUNDED DICHROMATIC NUMBER

GUILLAUME AUBIAN AND LUIS KUFFNER

**ABSTRACT.** We construct orientations of rook graphs (whose underlying graphs are claw-free) that contain no  $\vec{C}_3$  but have unbounded dichromatic number. This disproves a conjecture of Aboulker, Charbit and Naserasr and improves a result of Carbonero, Koerts, Moore and Spirk.

## 1. INTRODUCTION AND NOTATION

A hero is a tournament  $H$  such that tournaments not containing  $H$  have bounded dichromatic number. In a seminal paper [3], Berger, Choromanski, Chudnovski, Fox, Loeb, Scott, Seymour and Thomassé obtained a structure theorem for heroes. Harutyunyan, Le, Newman and Thomassé [7] later proved that oriented graphs with bounded independence number (tournaments being the special case where the independence number equals one) not containing a hero have bounded dichromatic number. Chudnovski, Scott and Seymour [6] subsequently showed that for any transitive tournament  $H$  and oriented star  $S$ , oriented graphs containing neither  $S$  nor  $H$  as induced subdigraphs have bounded dichromatic number. Aboulker, Charbit and Naserasr [2] thus wondered whether (and actually conjectured that), for any hero  $H$  and any oriented star forest  $S$ , oriented graphs containing neither  $S$  nor  $H$  as induced subdigraphs have bounded dichromatic number.

Aboulker, Aubian and Charbit [1] provided a counterexample when  $S = K_1 + \vec{K}_2$ . Carbonero, Koerts, Moore and Spirk [5] did so when  $H = \Delta(1, 1, C_3)$  and  $S$  is any orientation of  $K_{1,4}$ , and also when  $H = \vec{C}_3$  and  $S$  is any orientation of  $K_{1,5}$ . We improve these two latter results with a counterexample when  $H = \vec{C}_3$  and  $S$  is any orientation of  $K_{1,3}$ , i.e. the claw.

Definitions in this paper are standard and follow from Bondy and Murty's book [4]. In this paper, we study oriented graphs, i.e. directed graphs with no pair of opposite arcs. Given two integers  $n, i \geq 0$ , we write  $n_i$  for the  $i$ th least significant bit of the binary expansion of  $n$ , starting from  $i = 0$ .

## 2. CONSTRUCTION AND PROOF

Let  $N$  be a positive integer. The  $N \times N$  rook graph  $R_N$  is the graph with vertex set  $[1, N]^2$  and with an edge between two vertices whenever they share their first coordinate or they share their second coordinate. Intuitively, it is the graph describing how a rook moves on a  $N \times N$  chessboard. It is the line graph of  $K_{N,N}$ , and therefore is claw-free. We orient it into a digraph  $D_N$  as follows. For any vertices  $(a, b)$ ,  $(a, d)$ ,  $(c, b)$ , we orient the edge from  $(a, b)$  to  $(a, d)$  if and only if  $b_i = a_i$ , where  $i = \min\{j \mid b_j \neq d_j\}$ , and we orient the edge from  $(a, b)$  to  $(c, b)$  if and only if  $b_i \neq a_i$ , where  $i = \min\{j \mid a_j \neq c_j\}$ .

**Proposition 1.** *The digraph  $D_N$  contains no  $\vec{C}_3$ .*

*Proof.* Given three vertices  $(a, b)$ ,  $(a, c)$  and  $(a, d)$  on the same row, let  $i = \min\{j \mid \{b_j, c_j, d_j\} = \{0, 1\}\}$ . Without loss of generality let us assume that  $b_i \neq c_i = d_i$ . Edges  $(a, b)(a, c)$  and  $(a, b)(a, d)$  are oriented only depending on whether  $a_i = b_i$  and thus have the same orientation. Thus,  $(a, b)$ ,  $(a, c)$  and  $(a, d)$  can not form a  $\vec{C}_3$ . The same argument applies to any column. Since every triangle in a rook graph is contained entirely in a single row or in a single column,  $D_N$  contains no  $\vec{C}_3$ .  $\square$

**Lemma 1.** *When  $|a - c| = |b - d|$ , vertices  $(a, b)$ ,  $(a, d)$ ,  $(c, d)$ ,  $(c, b)$  induce a directed 4-cycle.*

*Proof.* Let  $i = \min\{j \mid |a - c|_j = 1\}$ . Then  $i = \min\{j \mid a_j \neq c_j\} = \min\{j \mid b_j \neq d_j\}$ . Up to permuting  $a$  and  $c$  and/or permuting  $b$  and  $d$ , we may assume  $a_i = b_i = 1$  and  $c_i = d_i = 0$ . Since  $b_i = a_i$ , we have  $(a, b) \rightarrow (a, d)$ . Since  $d_i \neq a_i$ , we have  $(a, d) \rightarrow (c, d)$ . Since  $d_i = c_i$ , we have  $(c, d) \rightarrow (c, b)$ . Since  $b_i \neq c_i$ , we have  $(c, b) \rightarrow (a, b)$ . Thus the four vertices form the directed cycle  $(a, b) \rightarrow (a, d) \rightarrow (c, d) \rightarrow (c, b) \rightarrow (a, b)$ .  $\square$

Note that it actually suffices that  $d_2(a, c) = d_2(b, d)$  where  $d_2$  is the dyadic distance, but this stronger condition suffices for the sake of our result.

**Theorem 1.** *The family  $(D_N)_{N \geq 1}$  has unbounded dichromatic number.*

*Proof.* Fix  $k$ . The Gallai–Witt theorem [8] (also known as the multidimensional van der Waerden theorem) implies that there exists  $N$  such that any  $k$ -colouring of  $[1, N]^2$  contains a monochromatic axis-parallel square, that is, four points of the form  $(x, y)$ ,  $(x + t, y)$ ,  $(x, y + t)$ ,  $(x + t, y + t)$  for some integers  $x, y, t > 0$ . Thus, for  $N$  large enough, any colouring of  $V(D_N)$  with  $k$  colours contains a monochromatic square as above. By the previous lemma, the four vertices of such a square induce a directed 4-cycle. Hence, some colour class does not induce an acyclic subdigraph. Since  $k$  is arbitrary, the dichromatic number of  $D_N$  is unbounded.  $\square$
